# The NAFEMS Challenge Problem

## A Challenge Problem on Uncertainty Quantification & Value of Information

A mathematical model of a typical electronic device as represented by a R-L-C network will be provided along with different levels of uncertainty estimates around the input parameters.

# The NAFEMS Challenge Problem

## A Challenge Problem on Uncertainty Quantification & Value of Information

A mathematical model of a typical electronic device as represented by a R-L-C network will be provided along with different levels of uncertainty estimates around the input parameters.

The objective is to assess the reliability of the device based on a set of criteria and also to quantify the value of information.

The output response is sensitive to the model parameters that have different cases of value of information.

# Problem statement

Typical electronic device represented by R-L-C network in series.

- ▶ **Input signal** Step voltage source for a short duration
- ▶ **Output response** Voltage at the capacitor ( $V_C$ )

Uncertainty estimates regarding the R, L, C values are available. The challenge is to evaluate the reliability of the device using two criteria:

- ▶ Voltage at a particular time should be greater than a threshold
- ▶ Voltage rise time to be within a specified duration

# The NAFEMS Challenge Problem

## In a nutshell

### Challenges:

- ▶ Deal with imprecision in the parameters data
- ▶ Assess quality of different information sources with respect to the reliability requirements

### Resources:

- ▶ Analytical solution for the system output is provided
- ▶ Different information sources are available for the system parameters

### Conclusions

# The Electrical Model

Typical electronic device represented by R-L-C network in series.

- ▶ **Input signal** Step voltage source for a short duration
- ▶ **Output response** Voltage at the capacitor ( $V_C$ )

Uncertainty estimates regarding the R, L, C values are available. The challenge is to evaluate the reliability of the device using two criteria:

- ▶ Voltage at a particular time should be greater than a threshold
- ▶ Voltage rise time to be within a specified duration

# The R-L-C Model

The transfer function of the system is:

$$\frac{V_c(t)}{V} = \frac{\omega^2}{S^2 + \frac{R}{L}S + \omega^2} \quad (40)$$

# The R-L-C Model

The transfer function of the system is:

$$\frac{V_c(t)}{V} = \frac{\omega^2}{S^2 + \frac{R}{L}S + \omega^2} \quad (40)$$

Roots are computed as:

$$S_{1,2} = -\alpha \pm \sqrt{\alpha^2 - \omega^2} \quad (41)$$

The system damping factor  $Z$ , parameter  $\alpha$  and  $\omega$  are determined as follow:

$$Z = \frac{\alpha}{\omega}; \quad \alpha = \frac{R}{2L}; \quad \omega = \frac{1}{\sqrt{LC}}; \quad (42)$$

# The R-L-C Model

## System response

Typical results: Under-damped,  
Critically-damped and  
Over-damped cases

# The R-L-C Model

## System response

Typical results: Under-damped,  
Critically-damped and  
Over-damped cases

Under-damped ( $Z < 1$ )

$$V_c(t) = V + (A_1 \cos(\omega t) + A_2 \sin(\omega t)) \exp^{-\alpha t} \quad (43)$$

Critically-damped ( $Z = 1$ )

$$V_c(t) = V + (A_1 + A_2 t) \exp^{-\alpha t} \quad (44)$$

Over-damped ( $Z > 1$ )

$$V_c(t) = V + (A_1 \exp^{s_1 t} + A_2 \exp^{s_2 t}) \quad (45)$$

# The R-L-C Model

Typical results: Under-damped,  
Critically-damped and  
Over-damped cases

For initial conditions  $\left. \frac{dV_c}{dt} \right|_{t=0} = 0$  and  $V_c(0) = 0$ :

# The R-L-C Model

Typical results: Under-damped,  
Critically-damped and  
Over-damped cases

For initial conditions  $\frac{dV_c}{dt} \Big|_{t=0} = 0$  and  $V_c(0) = 0$ :

$$V_c(t) = V + (-\cos(\omega t) - Z \cdot \sin(\omega t))e^{-\alpha t} \text{ if } Z < 1 \quad (46)$$

$$V_c(t) = V + (-1 - \alpha t)e^{-\alpha t} \text{ if } Z = 1 \quad (47)$$

$$V_c(t) = V + \left( \frac{S_2}{S_1 - S_2} e^{S_1 t} + \frac{S_1}{S_2 - S_1} e^{S_2 t} \right) \text{ if } Z > 1 \quad (48)$$

### Conclusions

# Reliability Requirements

Output of interest: The voltage at the capacitor

Reliability requirements on capacitance voltage ( $V_C$ ), rise time ( $t_r$ ) and damping factor ( $Z$ ):

1.  $V_C(t = 10ms) > 0.9 V$
2.  $t_r = t(V_C = 0.9V) \leq 8 ms$
3. System should not oscillate ( $Z > 1$ )

- ▶ Probability-boxes (
- ▶ Fuzzy Variables

# Possible solutions

## Imprecise probability approaches

### Parameter Characterisation

- ▶ Dempster-Shafer structures (D-S)
- ▶ Probability-boxes (
- ▶ Fuzzy Variables

### Uncertainty Quantification

- ▶ Double Loop Monte Carlo
- ▶ D-S combination and propagation (i.e. Cartesian product of all focal elements + output mapping, min-max search);
- ▶ P-boxes propagation by  $\alpha$ -cuts (i.e. focal element sampling + output mapping, min-max search);
- ▶ Robust Bayesian;
- ▶ Interval Analysis (e.g. min-max search)

# Examples Imprecise probabilistic approach

## **Focal Elements Propagation, Remark:**

In the procedure,  $m$ -dimensional interval input boxes are obtained (where  $m$  is number of focal elements sampled within each run).

The output is then mapped by min-max searched within the  $m$ -dimensional box. This can be done in many ways, for instance:

1. Approximate by sampling (e.g. MC, LHC);
2. Optimization techniques (e.g. Genetic algorithm, quad. prog.);
3. Vertex method and Interval Arithmetic methods;
4. For monotonic systems responses w.r.t input parameters, the min-max are on the input domain boundaries;

### Conclusions

# General Remarks

## Tasks

- ▶ Evaluate the reliability of the R-L-C device using the given criteria
- ▶ Quantify the value of information in each case
- ▶ You can use a technique/strategy of your choice
- ▶ Each approach comes with its own limitations that need to be evaluated.

A reference solution is provided and accessible via a stand-alone app (shown in the next slide). It provides a **possible solution** and **not** the “true” answers to the problem (that are unknown).

# Reference solution app

- ▶ Simple Stand alone application for the solution of the NAFEMS UQ Challenge problem
- ▶ Implement probabilistic approach (Monte Carlo) and D-S propagation

## Intervals

Information: 3 intervals one for each system parameter.

CASE-A	R [ $\Omega$ ]	L [mH]	C [ $\mu$ F]
Interval	[40,1000]	[1,10]	[1,10]

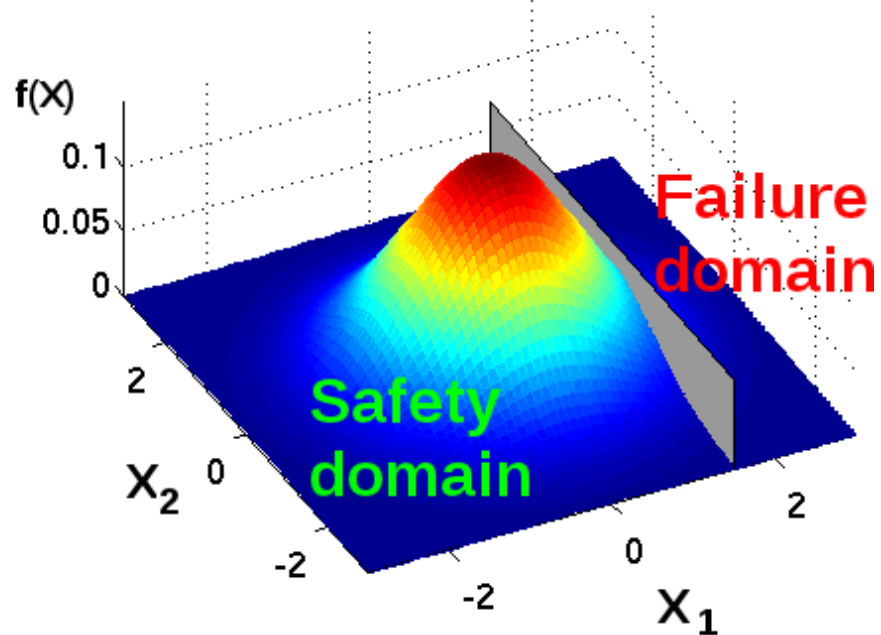

Provides reference solution obtained as follows:

Probabilistic approach:

- ▶ Maximum entropy principle, 3 uniform PDFs:  
 $R \sim U(40, 1000)$ ,  $L \sim U(1, 10)$ ,  $C \sim U(1, 10)$ ;
- ▶ Propagate uncertainty via Monte Carlo simulation

# Failure quantification

Bi-dimensional case

$$\int_{\mathcal{F}} f_{\mathbf{X}}(\mathbf{x}) d\mathbf{x} = \int \mathbb{I}_{\mathcal{F}}(\mathbf{x}) f_{\mathbf{X}}(\mathbf{x}) d\mathbf{x}$$

where:

$$\mathbb{I}_{\mathcal{F}}(\mathbf{X}) = \begin{cases} 0 & \iff \mathbf{X} \in \mathcal{S} \\ 1 & \iff \mathbf{X} \in \mathcal{F} \end{cases}$$

# Failure quantification

## Monte Carlo simulation

Evaluation (“dart” game):

- ▶  $f(x)dx$  probability to hit a point
- ▶  $\mathbb{I}_{\mathcal{F}}(x)$  the prize

# Failure quantification

## Monte Carlo simulation

Evaluation (“dart” game):

- ▶  $f(\mathbf{x})d\mathbf{x}$  probability to hit a point
- ▶  $\mathbb{I}_{\mathcal{F}}(\mathbf{x})$  the prize

- ▶ Estimate: direct Monte Carlo simulation

$$P_f = \int \mathbb{I}_{\mathcal{F}}(\mathbf{x}) f_{\mathbf{X}}(\mathbf{x}) d\mathbf{x} \approx \frac{1}{N} \sum_{k=1}^N \mathbb{I}_{\mathcal{F}}(\mathbf{x}^{(k)})$$

- ▶ to meet specified accuracy:  $N \propto \frac{1}{P_f}$

Estimate probability of failures :  $\hat{P}_{Vc10}$ ,  $\hat{P}_{tr}$ ,  $\hat{P}_Z$

# CASE-A

## Intervals analysis

Information: 3 intervals one for each system parameter.

CASE-A	R [ $\Omega$ ]	L [mH]	C [ $\mu$ F]
Interval	[40,1000]	[1,10]	[1,10]

- Explore range of variation for  $V_c(10ms)$ ,  $t_r$  and  $Z$  (min-max within input cuboid);

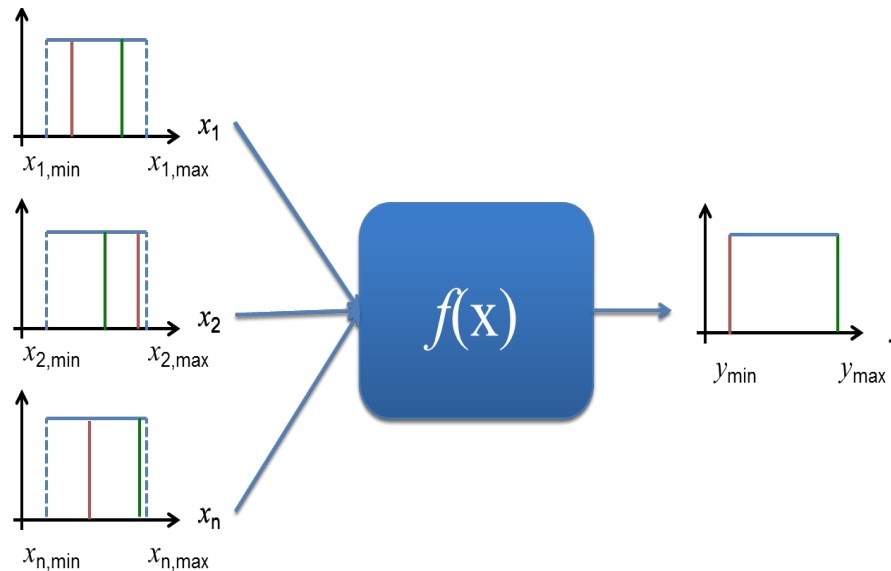

# CASE-A

## Sampled Points

Information available:

- ▶ 10 sampled values for each system parameter

Information:

CASE-C	R [ $\Omega$ ]	L [mH]	C [ $\mu$ F]
Sampled Data	861, 87, 430, 798, 219, 152, 64, 361, 224, 61	4.1, 8.8, 4.0, 7.6, 0.7, 3.9, 7.1, 5.9, 8.2, 5.1	9.0, 5.2, 3.8, 4.9, 2.9, 8.3, 7.7, 5.8, 10, 0.7

# CASE-C

## Sampled Points

Information available:

- ▶ 10 sampled values for each system parameter

Information:

CASE-C	R [ $\Omega$ ]	L [mH]	C [ $\mu$ F]
Sampled Data	861, 87, 430, 798, 219, 152, 64, 361, 224, 61	4.1, 8.8, 4.0, 7.6, 0.7, 3.9, 7.1, 5.9, 8.2, 5.1	9.0, 5.2, 3.8, 4.9, 2.9, 8.3, 7.7, 5.8, 10, 0.7

## Probabilistic approach

- ▶ PDF fitting for R,L and C (e.g. Kernel Density Estimation);
- ▶ Propagate uncertainty with MC and compute  $\hat{P}_{Vc10}$ ,  $\hat{P}_{tr}$ ,  $\hat{P}_Z$ ;

# CASE-C

## Kernel Density Estimation

Hypothesis: 10 samples  $x_1, x_2, \dots, x_{10}$  IID drawn from some distribution with an unknown density  $f$ .

$$\hat{f}_h(x) = \frac{1}{n} \sum_{i=1}^n K_h(x - x_i) = \frac{1}{nh} \sum_{i=1}^n K\left(\frac{x - x_i}{h}\right), \quad (49)$$

where  $K(\cdot)$  is the kernel,  $h > 0$  is a smoothing parameter called the bandwidth.

For Gaussian basis functions used to approximate univariate data, *Silverman's rule of thumb*:

$$h = \left(\frac{4\hat{\sigma}^5}{3n}\right)^{\frac{1}{5}} \approx 1.06\hat{\sigma}n^{-1/5}, \quad (50)$$

$\hat{\sigma}$ : standard deviation of the samples

Silverman, B.W. (1998). *Density Estimation for Statistics and Data Analysis*. London: Chapman &

Hall/CRC. p. 48. ISBN 0-412-24620-1.

# CASE-C

## Available information

Information available:

- ▶ 10 sampled values for each system parameter

Information:

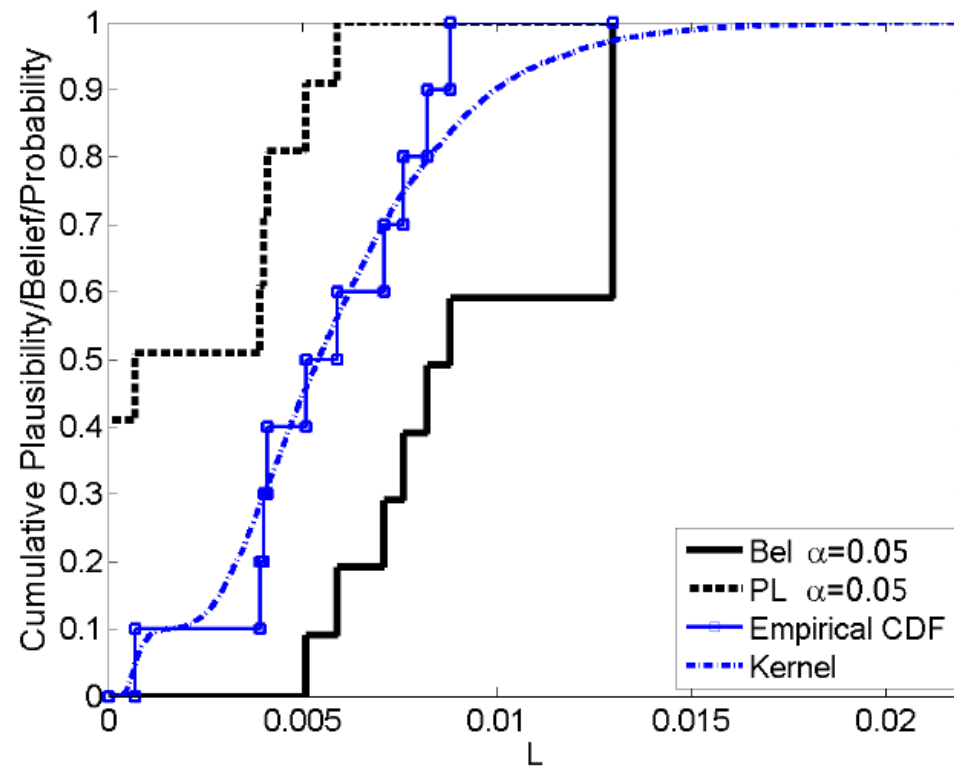

CASE-C	R [ $\Omega$ ]	L [mH]	C [ $\mu$ F]
Sampled Data	861, 87, 430, 798, 219, 152, 64, 361, 224, 61	4.1, 8.8, 4.0, 7.6, 0.7, 3.9, 7.1, 5.9, 8.2, 5.1	9.0, 5.2, 3.8, 4.9, 2.9, 8.3, 7.7, 5.8, 10, 0.7

## Imprecise probability

- ▶ Kolmogorov-Smirnov test (i.e. confidence bounds on the CDF and characterization using P-box);
- ▶ P-box propagation and compute  $\hat{P}_{Vc10}$ ,  $\hat{P}_{tr}$ ,  $\hat{P}_Z$ , which again are intervals;

## Probability Boxes

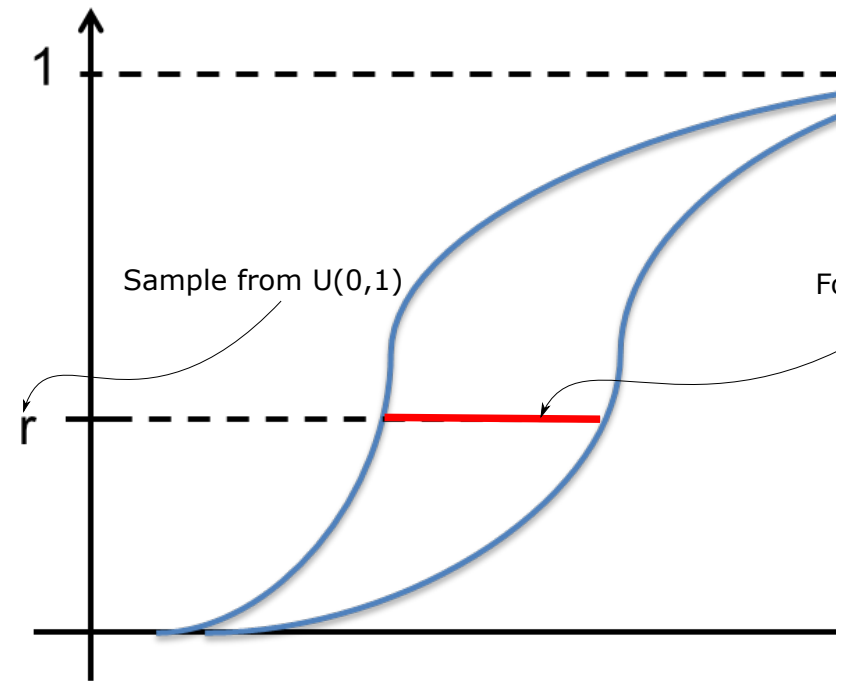

# CASE-C

## Bayesian Updating

$$P(\boldsymbol{\theta}|D, I) = \frac{P(D|\boldsymbol{\theta}, I) P(\boldsymbol{\theta}|I)}{P(D|I)} \quad (51)$$

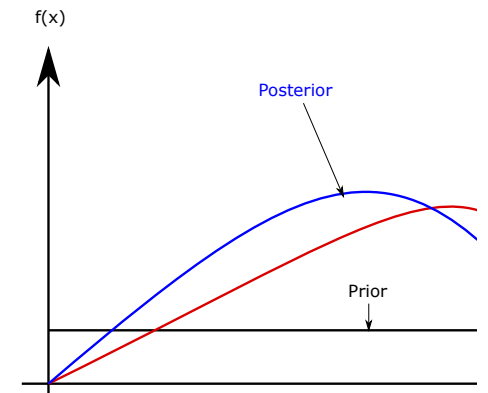

Bayesian Approach:

- ▶ Assume prior distribution (e.g.  $P(\boldsymbol{\theta}|I)$ ) as resulting from CASE-A)
- ▶ Collect data and compute likelihood

$$P(D|\boldsymbol{\theta}, I) = \prod_{k=1}^{N_e} P(x_k^e; \boldsymbol{\theta}) = \sum_{k=1}^{N_e} \log(P(x_k^e; \boldsymbol{\theta}))$$

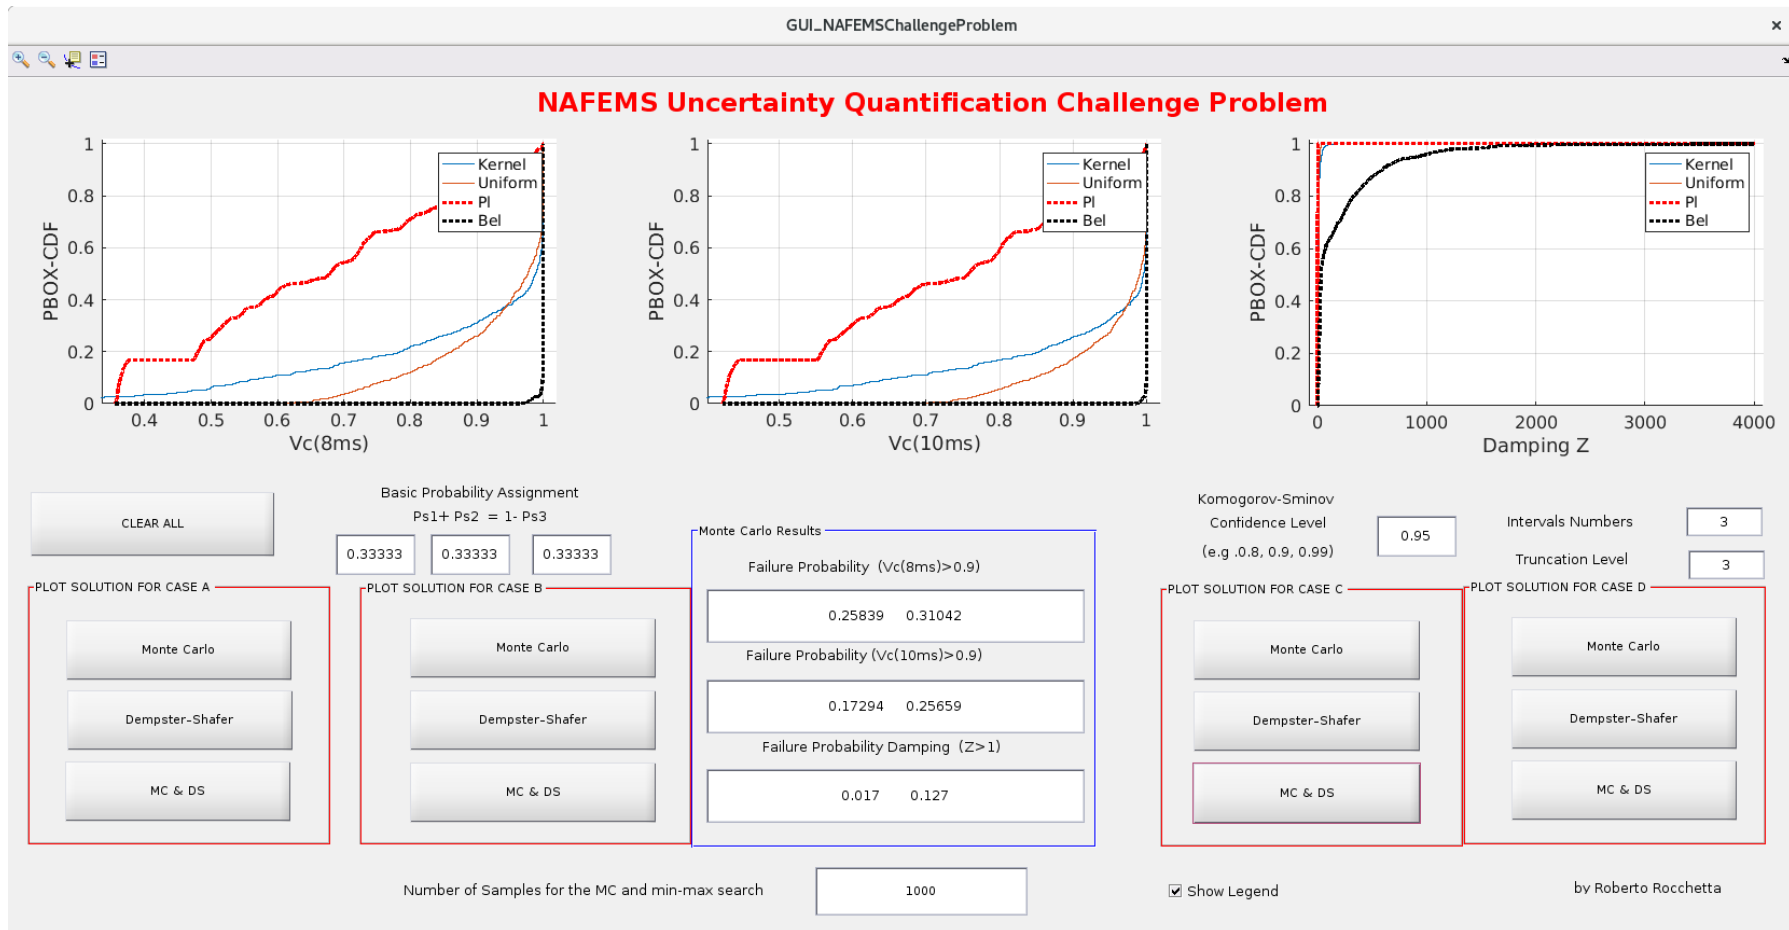

Compute Posterior  $P(\boldsymbol{\theta}|D, I) \propto P(D|\boldsymbol{\theta}, I) P(\boldsymbol{\theta}|I)$  for instance

$$P(x_k^e; \boldsymbol{\theta}) \propto \exp\left(-\frac{N}{\sum_{j=1}^N [f(\boldsymbol{\theta}, \omega_j) - f_k^e(\omega_j)]^2}\right)$$

Combine all available information

- ▶ Consider all the sources of information (CASE-A, CASE-B, CASE-C, CASE-D)
- ▶ Sampled values, nominal value and bounded and unbounded intervals

## Tasks

- ▶ Can we combine these sources of information?
- ▶ What is the effect of the reliability analysis?

# Hands-on of imprecise simulation in engineering

## Outline

### The NAFEMS Challenge Problem

The Electrical Model

Reliability Requirements

Available Information

Possible solutions (recap)

### Hands-on

General remarks and proposed solution

CASE-A

CASE-B

CASE-C

CASE-D

CASE-E

### Conclusions

# NAFEMS UQ CHALLENGE PROBLEM

Combine all available information

Quality of the information in each case?

- ▶ Check the output intervals

Propagation of uncertainty

Some final considerations:

- ▶ Information of case A and D seems to have the lowest quality ( $P_f$  interval about [0 1])
- ▶ CASE-C has the higher quality (narrower bounds on the output)
- ▶ Monte Carlo  $P_f$  lay within the bounds obtained by DS and P-box approaches
